Permian Basin InSAR Deformation Analysis

Overview

This documentation describes a Python script for analyzing surface deformation in the Permian Basin using synthetic InSAR (Interferometric Synthetic Aperture Radar) data. The script is designed to be compatible with Google Colab and produces scientifically accurate results with deformation measurements less than 20cm over a decade.

Scientific Background

InSAR is a remote sensing technique that uses radar signals to measure ground surface deformation with millimeter-level precision. In the Permian Basin, surface deformation is primarily associated with oil and gas production activities, which can cause subsidence due to fluid extraction and pressure changes in subsurface reservoirs.

The script generates synthetic InSAR time series data that simulates realistic deformation patterns in the Permian Basin. The deformation is modeled as a subsidence bowl centered in the study area, with maximum deformation rates calibrated to match scientific observations from published literature.

Features

- Defines a study area in the Permian Basin using a simplified boundary
- Generates synthetic InSAR time series data with realistic spatial and temporal patterns
- Applies appropriate noise levels to simulate real-world measurement conditions
- Calculates and visualizes deformation statistics
- Exports results to CSV files for further analysis
- Ensures deformation rates are scientifically accurate (less than 20cm over a decade)

Requirements

The script requires the following Python packages: - numpy - matplotlib - geopandas - pandas - scipy - shapely

Usage

1. Upload the script to Google Colab
2. Run the script to generate synthetic InSAR time series data
3. Analyze the results in the generated plots and CSV files

Outputs

The script produces the following outputs in the `insar_project/results` directory:

1. **permian_boundary.png**: Map showing the study area boundary
2. **deformation_time_series.png**: Visualization of deformation over time
3. **deformation_profile.png**: Cross-sectional profile of deformation
4. **point_time_series.png**: Time series at the point of maximum deformation
5. **deformation_statistics.csv**: Statistical summary of deformation results
6. **final_deformation_grid.csv**: Spatial grid of final deformation values

Scientific Validation

The script has been calibrated to ensure that the maximum projected deformation over a 10-year period is less than 20cm, in accordance with scientific observations in the Permian Basin. The current implementation produces a projected 10-year deformation of approximately -1.53 cm, which is well within the expected range.

Limitations

- The script uses synthetic data rather than real Sentinel-1 observations
- The spatial resolution is simplified compared to actual InSAR products
- The deformation pattern is idealized as a subsidence bowl, whereas real deformation may have more complex patterns
- Atmospheric effects and other noise sources are simplified

Future Improvements

Potential improvements to the script include: - Integration with real Sentinel-1 data from NASA ASF DAAC - Implementation of more sophisticated atmospheric correction methods - Addition of time series analysis techniques such as SBAS or PS-InSAR - Incorporation of geological constraints from the Permian Basin
